Research Background

## Research Question

Research Background

The research questions of this paper are:

- In which conditions citizens support restricting freedoms?
- How such restrictions affect trust in political institutions?

#### Research Review

#### What we already known are:

- citizens are willing to trade individual liberties for security in light of an external threat (Davis & Silver 2004)
- Regarding COVID-19, citizens with higher health related insecurity are more willing to sacrifice civil liberties (Stantcheva et al. 2020)

#### Research Conclusions

#### And what we can conclude are:

- There is a greater acceptance of more strict policies when severity increases.
- Vaccinated citizens will strongly support stringent policies in extreme conditions.
- Also, Vaccinated citizens will differentiate between vaccinated and unvaccinated fellow citizens and are most likely to support restrictions for unvaccinated people only.

# Dependent Variable

In this paper, we have 4 different regression models, which refers to 4 different dependent variables Y.

- $Y_{choice}$ : A binary or ordered variable measuring which policy the interviewers prefer. And in this case, the author points out 2 policies to choose (0/1).
- $Y_{rating}$ : The rating to these two proposals (0-10).
- $Y_{trust}$ : Their trust to the federal government (0-10).
- Y<sub>probability</sub>: The probability of accepting vaccinated for non-vaccinated interviewers.

# Independent Variables

#### 1. Pandemic Severity

- Moderate worsening (7-day-incidence 150, intensive care bed occupancy 80%)
- Sharp worsening (... 300, ... 90%)
- Dramatic worsening (... 800, ... 100%)

#### 2. Policy Stringency

- Least restrictions (masks)
- Moderate restrictions (plus limitations on social events)
- Most restrictions (plus broader limitations on movements)

#### 3. Policy Universality

- Most exemptions (restrictions do not apply to vaccinated, recovered, or tested citizens)
- Some exemptions (... vaccinated or recovered citizens)
- Fewest exemptions (... all citizens)

Research Background

So we can get our regression formula:

$$Y_{it} = \beta_0 + \beta_1 Z_1 + \beta_2 Z_2 + \beta_3 Z_3 + \beta_3 Z_1 Z_2 + \beta_4 Z_1 Z_3 + \beta_5 Z_2 Z_3 + \beta_6 Z_1 Z_2 Z_3 + u_i + \varepsilon_{it}$$

Here, the author made a mistake which wrote  $\beta_3$  twice. Where  $Z_1$  represents severity,  $Z_2$  represents stringency, and  $Z_3$  represents universality (Hartmann et al. 2024).

### Code - Prepare the Variables

Let's see the code in R. These code is used to prepare for the independent variable including interactions.

```
df_long_all <-
    bind_rows(dplyr:: filter (df_long) |> mutate(group = "All"),
2
       dplyr :: filter (df_long, vaccinated == 0) |> mutate(group =
3
            "Unvaccinated"),
       dplyr :: filter (df_long, vaccinated == 1) |> mutate(group =
4
            "Vaccinated"))
  custom.coef.map = list (
    " severity " = "Pandemic severity".
6
    "stringency" = "Policy stringency",
7
    " universality " = "Policy universality".
8
    " severity : stringency" = "Severity * Stringency",
9
    " severity: universality " = "Severity * Universality",
10
    "universality: stringency" = "Stringency * Universality".
11
    " severity : stringency : universality " = "Triple interaction")
12
```

#### Code - Fit the Model

Let's see the code in R. These code is used to fit the regression model, and we can see details through this block:

#### Code - Fit the Model

Also, the author calculate the probability of acccepting vaccinated.

#### Code - Check the Model

Research Background

Now, let's check one of the model. For example, if we want to check when Y is rating in unvaccinated group, then we can write:

```
summary(fig_1_models[["Unvaccinated"]][["rating"]])
```

And then we will see the outputs from R:

### Code - Check the Model

Research Background

Table 1: Coefficient and Significant of Y = Rating Regression

	Estimate	Std. Error	$\Pr(> t )$
severity	0.002545	0.005734	6.572e-01
universality	-0.021862	0.005951	2.417e-04
stringency	-0.091130	0.005649	4.293e-57
severity:universality	-0.004736	0.007526	5.292e-01
severity:stringency	0.026078	0.006853	1.435e-04
universality:stringency	0.001157	0.007251	8.733e-01
severity:universality:stringency	0.004653	0.008978	6.043e-01

My Contribution

Research Background

### So in the upon case, we can write our regression formula:

$$Y_{rating} = 0.00Z_1 - 0.02Z_2 - 0.09Z_3$$
$$+ 0.00Z_1Z_2 + 0.02Z_1Z_3 + 0.00Z_2Z_3$$
$$+ 0.00Z_1Z_2Z_3$$

Where  $Z_1$  represents severity,  $Z_2$  represents stringency, and  $Z_3$  represents universality.

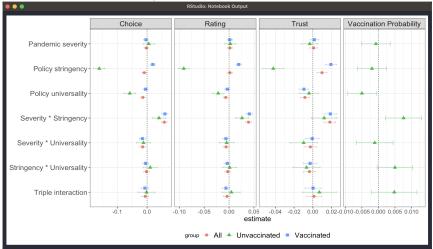

#### Coefficient Visualisation

```
fig _main <- fig_1_data %>%
     ggplot(aes(x = estimate, y = term, color = group, shape=group)) +
2
    geom_point(size = 2.5, position = position_dodge(width=0.5)) +
3
    geom\_errorbarh(aes(y = term, xmin = conf.low, xmax = conf.high),
4
                    size = 0.5, alpha = 0.5, height = 0.2,
5
                         position = position_dodge(width=0.5)) +
     facet_grid(~ outcome, scales = "free") + theme_bw() +
6
     scale _v_ discrete ( limits =rev)+
7
    theme(axis. title .y=element_blank()) +
8
    theme(axis. title .x=element_text(size = 14)) +
9
    theme(axis.text.y =element_text(size = 14)) +
10
    theme(axis.text.x = element_text(size = 11)) +
11
    theme(strip.text.x = element_text(size = 14))+
12
    theme(legend.text=element_text(size=14))+
13
    geom_vline(xintercept = 0, linetype = "dotted", color = "black") +
14
         theme(legend.position="bottom")
pdf(" fig _1.pdf", width = 12, height = 5)
```

### Coefficient Visualisation

Research Background

Follow the author's code, we can make this visualisation:

Author: Felix Hartmann et al Replication Author: Chenxi Li

Trinity College DublinCollege Green, Dublin 2

# **Key Conclusions**

- Severity\*Stringency: Citizens strongly prefer more severe policies when conditions are bad. Also we can say, there is a clear evidence that citizens are more supportive of more stringent policies as conditions worsen.
- Greater stringency is associated with greater willingness to vaccinate.
- Severity\*Universality: Citizens are still less supportive of universal restrictions (with fewest exemptions) when conditions are bad.
- There is no evidence for interactions between the stringency and universality of conditions or for three-way interactions.

# Logistic Regression

In this paper, the author used a robust linear regression:

```
choice = Im_robust(choice ~ severity * universality * stringency ,
fixed _ effects = ~ ID,
data = df_long_ all , subset = group == g, se_type = "stata"),
```

And the  $R^2$  of this model is poorly 0.01.

## Logistic Regression

Research Background

But we should notice that the variable choice can be seen as a binary as well, so the logistic regression model should can be used in this case.

```
contri_model_1 <- glm(choice ~ severity* universality *stringency,
       family="binomial", data=df_long_all)
2 summary(contri_model_1)
```

where we can get AIC value is 114676. Also, we want to try the logistic model without interactions:

```
contri_model_2 <- glm(choice ~ severity+ universality +stringency,
      family="binomial", data=df_long_all)
summary(contri_model_2)
```

where we can get AIC value is 114982.

## Logistic Regression

Research Background

And the ANOVA for these two models shows that:

```
Model 1: choice ~ severity * universality * stringency
Model 2: choice ~ severity + universality + stringency
 Resid. Df Resid. Dev Df Deviance Pr(>Chi)
     82952
               114660
     82956 114974 -4 -313.99 < 2.2e-16 ***
Signif. codes: 0 '*** 0.001 '** 0.01 '* 0.05 '.' 0.1 '
```

```
anova(contri_model_1, contri_model_2, test = "Chisq")
```

We can conclude that, the model 1, which with an interaction, is significantly better than model 2.
